Is the cell cycle a potential target for bleomycin-based radiosensitization of human lung cancer? Bleomycin (BLM) induces DNA damage and single-stranded DNA breaks, which are a prerequisite for the induction of chromosomal aberrations. Although DNA damage and chromosomal aberrations are thought to be the main causes of cell death in response to BLM, the possibility of a contribution by other factors has been proposed. If BLM itself or another drug or compound capable of producing a specific radiosensitizing effect also could affect the cell cycle, this could be an important mediator of the cytotoxic action of BLM. Human tumor cell lines NCI-H460, NCI-H226, and A549 of lung origin, which are relatively sensitive to BLM, were used. These cell lines were treated with BLM. In the TEMBL study, the cell cycle was monitored, and the chromosome aberrations were determined. In a second investigation, the effects of BLM on TEMBL and the cell cycle were studied. A relationship between TEMBL and BLM-induced chromosome aberrations was detected. The TEMBL was 30% +/- 8% 1 hr after treatment with BLM and 10%-35% 2-6 hr after treatment. BLM induced a significant perturbation of the cell cycle, ranging from 33% to 59% cells in G1 to 43% to 65% cells in S. BLM induced a significant increase in chromosome aberrations (from 1.7 to 4.6 per metaphase). There was a significant correlation between the TEMBL and the frequency of chromosome aberrations. These results indicate that the TEMBL accounts for the chromosome aberrations induced by BLM. We propose that the production of DNA damage and single-stranded DNA breaks by BLM, and possibly the cell cycle perturbation, may be important in the cytotoxic action of BLM-based radiosensitization. The clinically used BLM alone or in combination with cisplatin can produce cell

A lithographic apparatus is a machine that applies a desired pattern onto a substrate, usually onto a target portion of the substrate. A lithographic apparatus can be used, for example, in the manufacture of integrated circuits (ICs). In that instance, a patterning device, which is alternatively referred to as a mask or a reticle, may be used to generate a circuit pattern to be formed on an individual layer of the IC. This pattern can be transferred onto a target portion (e.g. including part of, one, or several dies) on a substrate (e.g. a silicon wafer). Transfer of the pattern is typically via imaging onto a layer of radiation-sensitive material (resist) provided on the substrate. In general, a single substrate will contain a network of adjacent target portions that are successively patterned. Known lithographic apparatus include so-called steppers, in which each target portion is irradiated by exposing an entire pattern onto the target portion at one time, and so-called scanners, in which each target portion is irradiated by scanning the pattern through a radiation beam in a given direction (the "scanning"-direction) while synchronously scanning the substrate parallel or anti-parallel to this direction. It is also possible to transfer the pattern from the patterning device to the substrate by imprinting the pattern onto the substrate. Radiation-sensitive resist layers are generally applied on a substrate or target portion to be imaged, such as a semiconductor wafer. Typically, radiation-sensitive resist layers are applied on an appropriate substrate or so-called "bottom" of the substrate, such as a wafer, so that the resolution of the imaged resist pattern is not limited by the characteristics of the substrate. However, the resist layers can be applied on the substrate at other locations, such as at 3da54e8ca3
